

# Interactive Lesson: Solving Simultaneous Equations by Elimination

Master the elimination method through step-by-step guidance, real-world examples, and interactive practice problems designed to build your confidence in solving simultaneous equations.

# What Are Simultaneous Equations?

## Two Equations, Two Unknowns

Simultaneous equations are pairs of equations containing two variables (like  $x$  and  $y$ ) that must be solved together to find unique values.

## Real-World Connection

Think of buying apples and bananas with a fixed budget - you need both prices to determine how many of each fruit you can afford.

# Why Choose the Elimination Method?

01

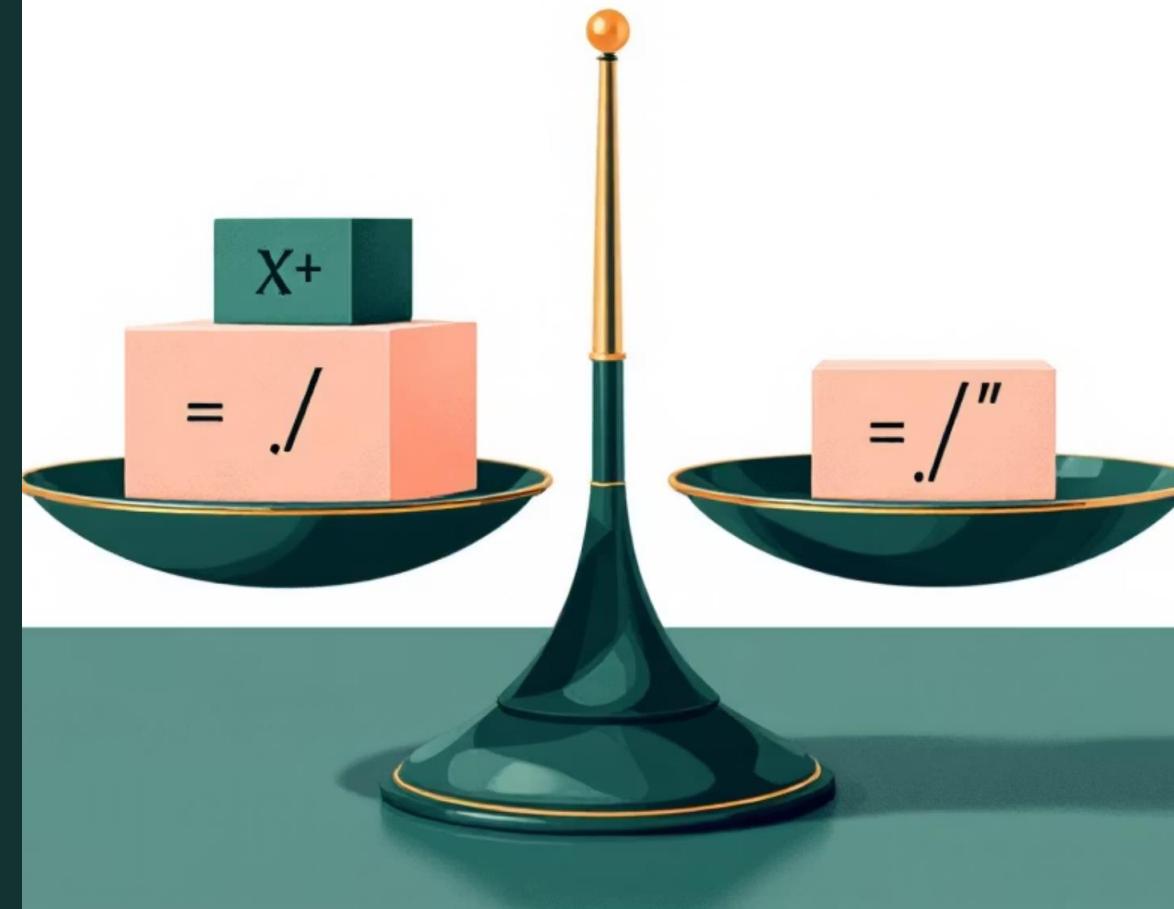

## Strategic Variable Removal

Elimination systematically removes one variable, making the problem simpler to solve than substitution in many cases.

02

## Clear Problem-Solving Path

Think of it as "canceling out" one unknown to solve the puzzle - like removing one weight from balanced scales to focus on the other.

# Step 1: Write Equations in Standard Form

Organize your equations with variables and constants properly aligned for easy manipulation.

$$3x + 2y$$

$$4x + = 30$$

## Example Setup

$$3x + 2y = 17$$

$$4x - y = 30$$

## Alignment Check

Ensure x-terms, y-terms, and constants are vertically aligned for clear visualization of the elimination process.

 $+ x = + 2$

## Step 2: Make Coefficients Opposite

Multiply one or both equations to create matching coefficients with opposite signs for the variable you want to eliminate.

1

Original Second Equation

$$4x - y = 30$$

2

Multiply by 2

$$8x - 2y = 60$$

Now the y-coefficients are  $+2y$  and  $-2y$ , perfect for elimination!

# Step 3: Add or Subtract to Eliminate

Combine the equations strategically - add when coefficients have opposite signs, subtract when they're the same.

Addition Process

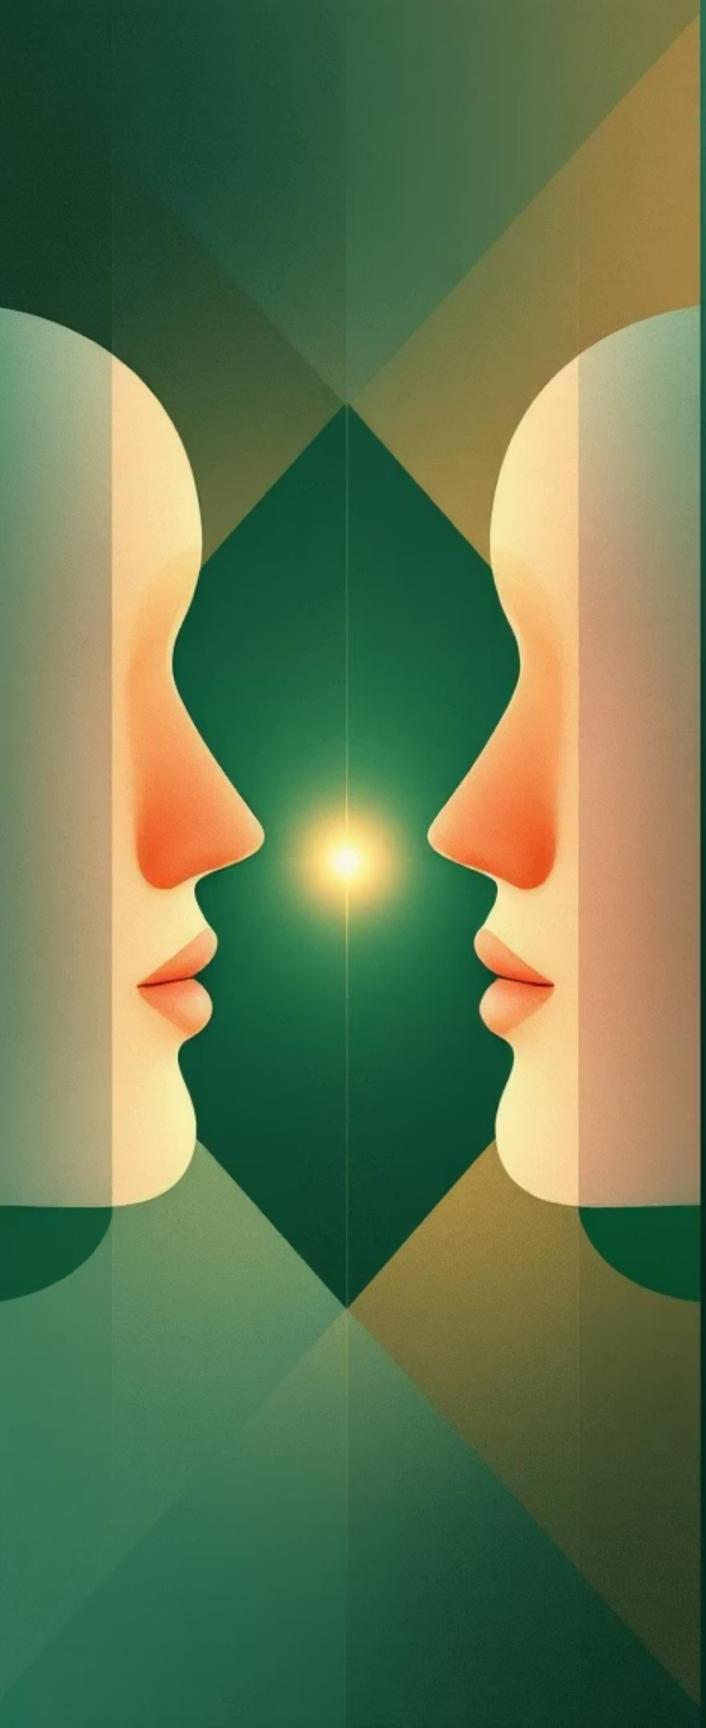

$$(3x + 2y) + (8x - 2y) = 17 + 60$$

Y-Terms Cancel

$$11x + 0y = 77$$

Simplified Result

$$11x = 77$$

# Step 4: Solve for the Remaining Variable

1

Find x

$$11x = 77 \rightarrow x = 7$$

2

Substitute Back

$$3(7) + 2y = 17$$

3

Solve for y

$$21 + 2y = 17 \rightarrow y = -2$$

4

Final Answer

$$x = 7, y = -2$$

## Real-Life Practice Scenario

Apply elimination to solve practical problems that mirror everyday decision-making.

“

### The Shopping Problem

You buy 3 apples and 2 bananas for \$17. Your friend buys 4 apples and 1 banana for \$30. What's the price of each fruit?

Use our elimination steps: Let  $x$  = apple price,  $y$  = banana price

”

This gives us the same equations we just solved: apples cost \$7 each, but bananas have a negative price - time to check our work!

$$\pm \begin{cases} x = 5, -5 \\ \downarrow \end{cases} \quad \frac{2^x - 1}{2^x + 1} < 0 \quad \frac{5^x - 1}{5^x + 1} > 0$$
$$1 \equiv \frac{x^2 - 1}{x^2 + 1} E +$$
$$y^2 - 25^2 = \frac{122}{x} + 0.1 - 12 \times 22 \quad x = (x) + q; x = 15 \quad 82, -x)$$

CORRECTED

## Common Mistakes & Pro Tips

### Sign Management

Pay careful attention to positive and negative signs when adding or subtracting equations - one wrong sign ruins everything!

### Always Verify

Substitute your final answers back into both original equations to confirm they work - this catches calculation errors.

### Choose Wisely

Pick the variable with simpler coefficients to eliminate first - it reduces the chance of messy fractions.

# Master the Method: Your Elimination Flowchart

01

Standard Form

Align variables and constants

02

Match Coefficients

Create opposite coefficients

03

Eliminate Variable

Add or subtract equations

04

Solve & Check

Find both variables and verify

Ready for the challenge? Try solving this system:  $2x + 3y = 13$  and  $5x - y = 7$ . Use elimination to find  $x$  and  $y$ !
